Suggestions for Fertilizing Spring Wheat and Soybean 2020

Dave Franzen, PhD
Professor Soil Science
NDSU Extension Soil Specialist
Fargo, ND
Spring wheat-
- Recommendations not yield-based
- Starter P is important
- Chloride of minor importance
- Micronutrients not important unless you farm where soil OM is >10%
Welcome to the
North Dakota Wheat Nitrogen Calculator

You will need to know the location of the farm, the general productivity of the soils, the price you contract for wheat, the cost per pound of N, the soil test nitrate-N to a depth of 2 feet, and the previous crop.

Please select the location of the farm. The map of North Dakota on this site will help you determine the region of the farm. Click on the map for a detailed view.

Low productivity is defined in Eastern ND as historical yields below 40 bushels per acre

Medium productivity is defined in Eastern ND as historical yields from 41 to 60 bushels per acre

High productivity is defined in Eastern ND as historical yields over 60 bushels per acre

Please indicate the crop previously planted in the field.

Select Nearest Wheat Price
(Brushel)

Nitrogen provided by previous crops

Please indicate the previous tillage method used in the field.
The nitrogen recommendation is the average optimal rate. Growers may choose to apply up to 30 lb N/acre more or less than the calculated N rates due to protein traits of a variety, special soil conditions such as susceptibility to spring denitrification, application techniques that may not be most efficient or historical experiences from the field or part of a field that may influence N uptake and efficiency. For wheat after small grains, we assume about 2,000 lb/acre of straw residue. For every 2,000 lb/acre straw greater than this, add 30 lb N/acre.
West Wheat Yield Under Conventional Tillage

\[ y = -0.0007x^2 + 0.1904x + 18.888 \]

\[ R^2 = 0.156 \]

West Wheat Yield Under Long-term No-Till

\[ y = -0.0007x^2 + 0.2601x + 23.085 \]

\[ r^2 = 0.19 \]
Why is the aggregated relationship of yield and available N so ‘diffuse’, when the relationships within sites are so highly related?
Combining all sites with actual yield at N rate looks like this.
When it really looks like this-
To get a better idea of what the data look like without showing all the curves is to ‘Standardize’ the data - putting it all in the same scale.

For example-
- A wheat site with high yield 80 bu/acre, divide all yields by 80, and we end up with values from 0 to 1.

- A wheat site with high yield 40 bu/acre, divide all yields by 40, and we end up with values from 0 to 1.

- A wheat site with high yield 60 bu/acre, divide all yields by 60, and we end up with values from 0 to 1.
Normalizing yields at all sites ends up looking like this:
Western ND No-Till wheat sites raw yields

\[ y = -0.0007x^2 + 0.2601x + 23.085 \]
\[ r^2 = 0.19 \]

Western ND No-Till wheat sites normalized yields

\[ y = -1E-05x^2 + 0.0041x + 0.5842 \]
\[ r^2 = 0.62 \]

Wheat Yield, bushels per acre

Total Known Available N, pounds per acre

Normalized Wheat Yields Within Sites

Total Known Available N, pounds per acre
Low yield environment-
usually drier (sometimes excessive wetness)
   Lower N use efficiency and crop uptake
   Less N mineralization

High yield environment-
   Moisture near ideal- not too wet or too dry
   Higher N use efficiency and crop uptake
   Greater N mineralization

Net result is that rate to produce economic max yield
is similar in both environments.
There is an app for Android and iPhones for the 3 N calculators, including wheat.

Go to app store and search for North Dakota Crop Nitrogen Calculator follow the instructions.

It’s free to download.
Don’t forget starter P for wheat

Chloride not important for wheat as it is for malting barley especially if soil test is low (<10 lb/a). Increases plump and helps to reduce effect of lower barley yield due to reduced kernel size.
Summary-

- Use of the N calculator for wheat for most profitable N rates. Use common sense to determine the rate best suited to your farm and variety.
- Yield goal is not a factor in N rate
- Band apply P
SOIL FERTILITY OF SOYBEAN - RECENT ND RECOMMENDATION CHANGES
Iron chlorosis is common in eastern North Dakota
• Iron chlorosis - yellowing between veins of youngest leaves.
• Chlorosis not seen until the 1\textsuperscript{st} tri-foliolate.
• Iron is mobile in the plant through the mono-foliolate stage.
The main form of iron (Fe) in soil is oxidized iron (Fe$^{+3}$).

Fe$^{+3}$ is a trillion times less soluble than Fe$^{+2}$.

Soybean roots secrete organic acids and H$^+$.

They also secrete a protein (enzyme) that reduces Fe$^{+3}$ to Fe$^{+2}$, increasing its availability to the soybean by a factor of 1,000,000,000.
But the protein is only effective if the pH is acid around the root!

If the soil pH is $> 7$, that means that the soil is dominated by carbonates.

(If soil pH $> 7$, carbonates are present)

\[
\text{CaCO}_3 \leftrightarrow \text{Ca}^{+2} + \text{CO}_3^{-2} \quad \text{[Neutralizes root acidity]}
\]

\[
\text{H}_2\text{O} + \text{CO}_3^{-2} \leftrightarrow \text{HCO}_3^{-1} + \text{OH}^{-}
\]

(water plus carbonate goes to bicarbonate and hydroxyl ions)
Additional stress causes increased IDC if carbonates are present and environment supports IDC development

(Wet soils, cooler soil temps, herbicide stress).
Soybean yield is reduced to about 85% even without IDC at EC 1.5

\[
y = -13.972x^2 + 16.749x + 89.361
\]

\[
R^2 = 0.2795
\]
Field selection-

1. Fields with low carbonates or slightly acid soils preferred. (<7.2)

2. Select fields with EC no higher than 1.5

3. Select fields with decent drainage.

Soybean Soil Fertility, Franzen et al., 2019
Inoculation is not necessary or helpful if the field has been in a successfully nodulated soybean field within the past 4 years.

Supplemental N is not helpful unless the nodulation is a total disaster and the leaf tissue indicates N deficiency.
Rescue N application only profitable on virgin ground or no nodulation. R3 N application

Endres, Aberle, and Henson, 2002
P is only needed for yield increase when soil test is 7ppm or less.

Broadcast or band-seed separated P is best.

Seed-placed P does not increase yield in most trials and can decrease yield especially if the soil becomes dry after seeding.

*Endres and Hendrickson, 2008*
There is no safety advantage of ‘low-salt’ starters compared to 10-34-0 based starters.

‘Low-salt’ starters contain urea or UAN, which is at least as harmful to the seed as salt.

Soybean Soil Fertility, Franzen et al., 2019
K rates are based on clay chemistry in North Dakota. The circular has a map that can serve as a guide to rates.
Smectite:Illite Potassium Thresholds
In-season foliar sprays for N, P, K are almost never effective at $ payback let alone profit.

2 treatments each site in NC and NW ND, 6 site years- no effect on yield at 2 different timings (2016-2019).
Soybean is much more able to extract S from the soil compared to wheat or corn.

Soybean may respond after a year like 2019 and snow like so far in 2020 on SANDY, higher topography location soils.

Rescue of S deficient soybean is possible in-season (soybean is an August crop).
NDSU finds no need for micronutrient supplements in North Dakota.  

Except Fe
Fe-o-o-EDDHA is the best so far iron fertilizer for soybean-in-furrow at seeding. Follow label directions. Try to use a product with the highest ortho component.

Take care of field selection, variety selection first before using Fe fertilizer to overcome IDC.
FeEDDHA Fertilizer Quality
